## Abstract

Covid-19 pandemic forced all the world to make significant changes in their daily routines. As a result, internet and digital technologies started to be used more actively by individuals and businesses. Due to this digitalization, everyone is more open to digital threats. In order to provide the security of the network, firewalls should be used. Firewalls act as a barrier between the internal and the external networks. Thus, it is more important than ever to choose the right firewall for each network. In this study, an integrated Fuzzy-Analytic Hierarchy Process (AHP) and TOPSIS model is introduced to find out the most suitable firewall. A survey is designed and used to generate the data of this study. This study distinguishes from other studies by proposing a solution which ranks the firewall alternatives using a combination of fuzzy-AHP and TOPSIS models. As a result, among the five different firewall alternatives, the second one is found out to be the best. A solution proposal ranking the firewall alternatives is new in the literature. This approach is used in many different Multi-Criteria Decision Making (MCDM) problems before but not in firewall selection. Hence, this study can be considered quite innovative in terms of the problem it handles and the model used. It offers a new solution related to a decision making problem that has started to gain more importance with the current digitalization process due to Covid-19 pandemic.

**Keywords:** Fuzzy-AHP, Topsis, Firewall, Multi-criteria decision making.

## 1 | Introduction

Internet was a disruptive technology that changed the world drastically. The operation of businesses, communication of individuals and many other routines evolved as a result of the development of internet. Especially, the Covid-19 pandemic increased the usage of internet radically. It required businesses operate online, students take classes online and individuals work remotely connecting to the corporate networks. Since all the world is continuing their daily lives online, cyber security attacks increased and as a result, everyone is more vulnerable to digital threats compared to pre Covid-19 period. Therefore, it is very important to provide the security of the network whether it is a corporate or an individual one.

Specifically, corporate networks should be protected from undesired access because a study found out that 70% of cyber attacks targeted network cloud services and resources in [1]. A “Firewall” should be used to secure a network. It is a defense device combined of software and hardware products that protect any network from outsider’s unauthorized access [2]. Firewalls define, control and limit the access to the available network so they basically act as a gateway between the internal and the external network [2] and [3].

The most important feature of a firewall is to keep the resources secure within the network behind the firewall. Also, a firewall should have the spoofing protection, network address encryption, user authentication, data encryption, bandwidth management and digital signature [2]. In large corporations, more than one network administrator is responsible from the operation of the network [4]. However, it is difficult to preserve a consistent strategy when there are many people responsible from the same tasks. Therefore, the human error factor is too much to ignore in the configuration of networks and the firewalls. According to a study, sixty percent of security breaches in 2019 were caused by network administrators' mistakes [1]. Thus, extra care should be given while setting up the firewall and ensuring the network security. Network administrators mainly consider the following while choosing their firewall needs; cost, performance, technical support, scalability, ease of use and configuration, remote and basic access control, preventing denial-of-service attacks and tracking logs of internet usage [2], [3] and [5]. However, the major factor for many corporations in the selection of firewall is the cost vs performance balance [5].

The rapid development of technology provided many opportunities to everyone. While this seems great, it actually creates the paradox of choice [6] because decision makers had to evaluate all the alternatives before making a decision in order to choose the best option for their needs [7]. Hence, decision makers prefer to get assistance from the software systems called Decision Support Systems (DSS). These systems receive certain data as input, evaluate the data, perform necessary calculations and deliver the best alternative as an output. DSS can use many different models in its calculations. Among most well known model in Multi-Criteria Decision Making (MCDM) is AHP. It deals with complex issues that include both qualitative and quantitative considerations. It was developed by Saaty [8] and uses a pairwise comparison method to find the corresponding weights of each criteria which are part of the decision making model. Also, AHP systematizes the most important elements of an issue into a hierarchy, similar to a family tree [9].

Fuzzy set theory is applied to model the ambiguity and vagueness in decision making problems surfacing due to the subjectivity of human judgement [10]. Linguistic terms are used to indicate the preferences of the decision maker. The first scholars who study the decision-making problem with fuzzy sets were Zadeh and Bellman [11]. Fuzzy-AHP started to be used based on fuzzy set theory to eliminate the uncertainties of the AHP technique. The first studies using fuzzy-AHP method was performed by Van laarhoven and Pedrycz [12]. Later on, other academics also used and developed this model in different decision making problems [13]-[18]. For pairwise comparisons, Chang [13] introduced Triangular Fuzzy Numbers (TFN). TFNs based on geometric means are used in this paper to evaluate the preferences of decision makers because it is easier to realize and measure using TFNs.

TOPSIS stands for Technique for Order Preference by Similarity to Ideal Solution. This method was first used by Hwang and Yoon [19]. It is a multi-criteria method for deciding on the best alternative from a limited number of possibilities. The main principle is that the chosen alternative should be the closest to the Positive Ideal Solution (PIS) but should be the furthest away from the Negative Ideal Solution (NIS) [20]-[22]. Due to its comparatively simple mathematical approach, TOPSIS is a highly preferred technique [23]. It has, however, been chastised for its inadequacy in dealing with ambiguous problems [24]. Nonetheless, fuzzy logic-based solutions, such as the fuzzy AHP, can overcome the issues that arise during the subjective evaluation process. Fuzzy AHP is also commonly employed in real world scenarios to tackle decision-making issues. As a result, this study devised an integrated process that combines the fuzzy AHP and TOPSIS methods. The criteria weights were determined by fuzzy AHP in the first phase of the proposed approach, and the alternatives were ordered using TOPSIS in the second phase.

The aim of this study is to initially outline the main decision criteria for selecting a firewall and then rank the alternative product offers that can meet the firewall needs of an institution. Considering the previous studies mentioned above, it is seen that the integrated fuzzy-AHP and TOPSIS approach is applied in several different decision making issues in many different fields, but not in this one. A solution proposal ranking the firewall alternatives is new in the literature. For this reason, this study distinguishes from others by providing network administrators a new perspective for selecting the best firewall alternative for their institutions.

The rest of this study is organized as follows. Section 2 contains the methods which is about the fundamentals of AHP, fuzzy set theory, TOPSIS and the proposed integrated approach. Section 3 describes the data collection process. Section 4 represents the findings and the results. Finally, Section 5 states the conclusion and mentions future research opportunities.

## 2 | Methods

This paper deals with a MCDM problem and it will use the combination of fuzzy-AHP and TOPSIS approaches to explain this problem and will choose the best firewall alternative among several different options. Fuzzy-AHP is the merge of two different methods; fuzzy set theory and AHP. This method will be integrated with TOPSIS in order to rank the firewall alternatives.

### 2.1 | Analytical Hierarchy Process (AHP)

AHP is a well known MCDM technique to rank the decision alternatives. In AHP, you develop a hierarchy starting from upper level criteria and go one level down with each subcriteria and at the bottom level, you sort the alternatives. All of the criteria and subcriteria along with alternatives are then compared pairwise using a scale from 1 to 9 that transforms the choices of humans among existing alternatives as equally, weakly, moderately, strongly and very strongly. In the pairwise comparison matrix, a value of 9 states that one factor is extremely more important than the other, a value of 1/9 states that one factor is extremely less important, and a value of 1 states that both factors are equally important [25]. Despite its success and logical simplicity, this approach is frequently criticized for its incapability to effectively manage the ambiguity related with decision makers' perspective to exact numbers [14], [17] and [26]. Fuzzy set theory is introduced to remove this restriction, and started to be used with AHP method.

### 2.2 | Fuzzy AHP

The fuzzy-AHP method is an advanced technique using the fuzzy set theory designed to handle the ambiguities and uncertainties in decision making problems. A membership function, that allocates each object a degree of membership between 0 and 1, characterizes a fuzzy set. The terms 'large, medium, and small' are applied to capture a scope of numerical values in this set [17]. Chang presented TFNs for expressing the smallest and largest possible number of each scale in a pairwise comparison [13]. This study is based on Chang's approach of TFNs. It uses crisp values 1, 3, 5, 7, 9 as the geometric means of each linguistic term and calculate the TFNs for each one accordingly. In line with this calculation, "equally" is represented as (1,1,1), "weakly" is represented as (2,3,4), "moderately" is represented as (4,5,6), "strongly" is represented as (6,7,8) and "very strongly" is represented as (9,9,9).

### 2.3 | TOPSIS

TOPSIS is a simple and easy-to-implement MCDM strategy that is implemented when the user prefers a simpler weighting approach. This method ranks the alternatives and identifies the best alternative which is close to the PIS and far from the NIS. PIS denotes a solution that maximizes benefit criteria while minimizing cost criteria, whereas NIS denotes a solution that maximizes cost criteria while minimizing benefit criteria [27]. The TOPSIS technique considers both PIS and NIS distances, with the

best option being the one that is geometrically closest to PIS and farthest from NIS [28]. Alternatives are graded based on how closely they resemble the ideal solution, avoiding the situation when one option is comparable to both PIS and NIS.

## 2.4 | Proposed Approach

In this study, a two-step approach is used integrating fuzzy-AHP and TOPSIS methods. The linguistic preferences of experts are mapped with TFNs using the fuzzy-AHP approach to decide the preferences and relevance of one criterion over another. The fuzzy-AHP method uses a decision hierarchy and pairwise comparisons between criteria. The alternatives are then ranked using TOPSIS based on their overall performance. There are many studies in the literature that combines these two techniques together in order to solve complex MCDM problems [29]-[33]. The proposed approach is as follows:

- *The linguistic preferences of experts are transformed into TFNs in order to compare the alternatives.*
- *Using the fuzzy-AHP approach, pairwise comparisons of criteria and alternatives are calculated in order to find out the weight vectors of criteria and decision alternatives.*
- *TOPSIS method is used to normalize the decision matrix, calculate PIS and NIS and finally, rank all of the alternatives.*

## 3 | Data Collection

The data collection phase is divided into two parts. In the first part, data were collected from five experts to determine the criteria used in the decision model and the importance (weighting coefficients) of those criteria. In the second part, bids were collected from suppliers in order to identify the alternative services to be used in the model.

During the first stage of data collection, face-to-face interviews were conducted with various experts working in public and private sectors to assess the criteria to be used in the decision-making model. The survey asked for the weight coefficients of the criteria in three main groups and the weight coefficients of the subcriteria for each group. The characteristics of the five experts participated in this research were as follows; one expert was working as a faculty member at the university, two were engineers and the other two were managers. The expert with the least professional experience was an engineer with 5 years of experience and the most experienced was an IT manager with 28 years of experience. The average professional experience of experts was 16 years.

At the second stage, suppliers providing corporate firewall services were contacted. Pricing and service details were requested for a firewall to be used in a cyber-security laboratory to be constructed at the university. Bids were received from service providers as proforma invoices. Collected bids can be seen in *Table 1*. Afterwards, a hierarchical structure showing criteria and sub-criteria was constructed for selecting the best firewall alternative problem. This structure is shown in *Fig. 1*.

**Table 1. Collected firewall alternatives from service providers.**

ALT.	Cost Price (USD)	Licence Fee (USD)	After Warranty Support Fee (USD)	Licence Term (Year)	Capacity Number of Users	Number of Sessions	Band Width (Mbps)	Productivity Total Cost Per User (USD)	Total Support Cost Per User (USD)

## 4 | Results

### 4.1 | Fuzzy AHP Results

In order to determine the best firewall service provider among the alternatives, initially, the fuzzy comparison matrix of the main criteria was developed by a pairwise comparison relevant to the overall goal; given on *Table 2*.

Following the comparison of main criteria, the comparison matrices of subcriteria regarding each main criterion were constructed. *Table 3* shows the fuzzy comparison matrix of the subcriteria and the weights of each subcriterion in regard to main criterion C1 as an example. A total of 3 matrices were constructed for all subcriteria with regard to their main criterion.

Table 2. The fuzzy comparison matrix of main criteria in regard to the overall objective.

O	C1	C2	C3	Weight
C1	1.0, 1.0, 1.0	1.0, 1.0, 1.0	1.0, 1.0, 1.0	0.318
C2	1.0, 1.0, 1.0	1.0, 1.0, 1.0	0.25, 0.33, 0.50	0.226
C3	1.0, 1.0, 1.0	2.0, 3.0, 4.0	1.0, 1.0, 1.0	0.457

\*C1: Cost, C2: Capacity, C3: Productivity

Also, the fuzzy comparison matrices of the firewall alternatives and the weight of each alternative in relation to the corresponding subcriteria were also constructed. *Table 4* shows the alternatives' fuzzy comparison matrix regarding subcriterion C11. A total of 9 matrices were constructed for all alternatives in regard to their subcriteria.

**Table 3. The fuzzy comparison matrix of the subcriteria in regard to main criterion C1.\***

## 4.2 | TOPSIS Results

In order to rank the alternative locations, the TOPSIS approach is used. TOPSIS uses the fuzzy AHP-calculated priority weights of alternative firewall services with respect to criteria, as shown in *Table 6* below. *Table 7* displays the weighted normalized decision matrix.

**Table 6. The priority weights of alternative services with respect to criteria.**

	C1	C2	C3
<b>A1</b>	0.243140203	0.068287289	0.413816441
<b>A2</b>	0.199192236	0.105126926	0.413816441
<b>A3</b>	0.161725021	0.179397788	0.034640886
<b>A4</b>	0.14292085	0.179397788	0.065099432
<b>A5</b>	0.253021692	0.46779021	0.072626801

**Table 7. The weighted normalized decision matrix.**

	C1	C2	C3
<b>A1</b>	0.168769924	0.028166048	0.318115089
<b>A2</b>	0.1382645	0.043361071	0.318115089
<b>A3</b>	0.112257533	0.073995127	0.026629654
<b>A4</b>	0.09920507	0.073995127	0.050044197
<b>A5</b>	0.175628922	0.192946615	0.055830748

The ranking of alternative services is calculated below using the TOPSIS algorithm. *Table 8* provides the results of the examination and the final ranking of firewall service choices.

**Table 8. TOPSIS decision matrix showing the best alternative.**

	$S_i^*$	$S_i^-$	$C_i$
<b>A1</b>	0.164923258	0.299671534	0.645016988
<b>A2</b>	0.1541815	0.294483084	0.656354645
<b>A3</b>	0.321137274	0.047651561	0.129210965
<b>A4</b>	0.303071055	0.05146402	0.145159177
<b>A5</b>	0.262284342	0.183972673	0.412257212

The final score showed that firewall service provider alternative A2 is the most convenient provider followed by alternative A1. Hence the integrated Fuzzy-AHP and TOPSIS models revealed that the problem of corporate firewall service provider selection can be addressed in a systemic and effective manner.

## 5 | Conclusion

In this study, a multicriteria decision support model was used for the process of determining a proper firewall service provider, which is a problem that IT experts and managers have difficulty in making decisions.

This study was conducted to determine the most suitable service among the alternatives that can satisfy the firewall requirements of an institution and have technically similar features. In order to tackle this, the data received from experts working as managers, academics and engineers were used. Cost, capacity, productivity criteria and their respective subcriteria were evaluated by experts. The alternative service providers used in this study were generated by using the actual data in the price offer received from the sales distributors in order to reflect the real market conditions. Using the suggested criteria and the data obtained, alternatives were listed using the combination of fuzzy-AHP and TOPSIS approaches and the calculation steps in the rankings were presented.

The fuzzy-AHP model considered in this study has been shown to be simple, less time-consuming and requiring less computing power [13]. Fuzzy-AHP does not require complex mathematical operations, making it simple to deal with multi-attribute decision-making issues like choosing a firewall service provider and TOPSIS is an easy to use method to rank the alternatives and identify the best one which is close to the PIS and far from the NIS. Therefore, in this study the combination of these two approaches are preferred in order to reach the best solution.

Considering the previous studies mentioned in the introduction, a solution proposal ranking the firewall service provider alternatives is new in the literature. Hence when this study is considered to be a decision-making problem which has not been previously discussed in the literature, it differentiates from others by providing network administrators a new perspective for selecting the best firewall alternative for their institutions. In future studies, the alternatives of this study can be extended and more firewall alternatives can be added or different methods can also be conducted and all of these methods can be compared amongst each other to address the issue of choosing a proper firewall alternative. In addition, the method utilized here may be applied to other decision-making problems in different fields and other industries may also use this method.
